Adaptive Retrodiction Particle PHD Filter for Multiple Human Tracking

Pengming Feng, Student Member, IEEE, Wenwu Wang, Senior Member, IEEE, Syed Mohsen Naqvi, Senior Member, IEEE, and Jonathon Chambers, Fellow, IEEE

Abstract—The probability hypothesis density (PHD) filter is well known for addressing the problem of multiple human tracking for a variable number of targets, and the sequential Monte Carlo (SMC) implementation of the PHD filter, known as the particle PHD filter, can give state estimates with non-linear and non-Gaussian models. Recently, Mahler et al. have introduced a PHD smoother to gain more accurate estimates for both target states and number. However, as highlighted by Psiaki in the context of a backward-smoothing extended Kalman filter, with a non-linear state evolution model the approximation error in the backward filtering requires careful consideration. Psiaki suggests to minimise the aggregated least-squares error over a batch of data. We instead use the term retrodiction PHD (Retro-PHD) filter to describe the backward filtering algorithm in recognition of the approximation error proposed in the original PHD smoother, and we propose an adaptive recursion step to improve the approximation accuracy. This step combines forward and backward processing through the measurement set and thereby mitigates the problems with the original PHD smoother when the target number changes significantly and the targets appear and disappear randomly. Simulation results show the improved performance of the proposed algorithm and its capability in handling a variable number of targets.

Index Terms—adaptive filter, PHD filter, Retro-PHD, multiple human tracking.

I. INTRODUCTION

VIDEO signal processing based human tracking is becoming increasing popular because of its wide potential applications. However, tracking multiple human targets has many challenges such as variable number of targets, targets occlusion and target states estimation. To solve these challenges, especially the variable number of targets, one way is to find explicit associations between measurements and targets, and then to filter the measurement to individual targets[1]. However, due to the additional processing required for the estimation and data association for each individual target, the computational complexity of these methods grows exponentially with the increase in the number of targets[2]. Based upon the concept of a Random Finite Set (RFS) [3], the PHD filter [4] is proposed to handle the varying target cardinality and to reduce the computational complexity by only employing the first-order moment of the posterior density [5]. The PHD is the intensity function of a finite point process and, in practice, both the number of targets and their states are extracted from the PHD surface, which is a spatial distribution of target number [5][6]. However, as mentioned in [7], the PHD filter depends on the current measurement set, so in the case of a low number of observable measurements, its performance is limited.

In order to achieve more observable measurements, a forward-backward filtering algorithm has been utilized for the particle PHD filter [8][9], which provides backward estimation from the aid of delayed measurement set. Improved performance has been shown in [8] and [9] by employing the PHD smoothing algorithm in multiple target tracking. However, in [10], Psiaki has pointed out that, when using the smoothing algorithm for a nonlinear filtering system, it is necessary to consider a batch of data and minimize the aggregated error over the batch at each time step to mitigate the approximation error. As a consequence, when attempts backward processing with embedded approximations (such as in PHD smoothing, with a nonlinear state model) the use of the term smoother should be avoided. So in this letter, we adopt the term retrodiction to represent the backward filtering process in [9]. When evaluating the Retro-PHD algorithm, we found although the approach can improve the tracking results over the PHD filter; its performance deteriorates with an increasing number of targets appearing and disappearing in the monitored area. In such a scenario, more false measurements for backward estimation are introduced by false alarm or missed detection.

Adaptive filters [11][12] on the other hand are a widely used signal processing technique for their exploitation of recursion in tracking [11]. Following the idea of combination of adaptive filters proposed in [11], in this letter, a new method for the Retro-PHD filter is proposed by using an adaptive recursion step, in which the measurements from both forward and backward processing are employed for target state estimation. Measurements are utilized to calculate the adaptive weights, which are then used to enhance the tracking results. Simulations using sequences from the CAVIAR [13] and the PETS2009 [14] datasets will show that the proposed adaptive Retro-PHD outperforms the state-of-art particle PHD filter and the original Retro-PHD filter [9]. Other recent multiple human target trackers such as cardinality PHD filter [15] and multi-Bernoulli filter [16] are not included in this short study as they do not involve backward/retrodiction processing.
II. SMC PHD FILTERING AND RETRO-PHD FILTERING

A. Particle PHD filtering

In this work, the particle PHD filter is employed for tracking because it performs well in the scenarios of non-Gaussian noise and non-linear models [17]. We assume the set of targets \( \{ x_m^k \}_{m=1}^{M_k} \) includes the states of all the human targets, where \( M_k \) is the number of targets at time \( k \) and \( m \) is the target index. Denote the measurement set at time \( k \) as matrix \( Z_k \), which includes vector \( z_k \) as each individual measurement. The basic principle of importance sampling in the particle filter is to represent a PDF \( p(x_k|Z_k) \) by a set of random particles \( x_k^i \) having associated weights \( w_k^i \), where \( x_k = \{ x_k^i, i = 1, ..., N \} \), which denotes all \( N \) particles utilized to describe the states of all human targets at time \( k \) [18], and for each particle, \( x_k^i = [p_{k,x}^i, p_{k,y}^i, v_{k,x}^i, v_{k,y}^i, h_k^i, w_k^i]^T \in \mathbb{R}^6 \) denotes the state of the particle at discrete time \( k \), including the 2D position \( [p_{k,x}^i, p_{k,y}^i] \), velocity \( [v_{k,x}^i, v_{k,y}^i] \), height and width of targets \( h_k^i, w_k^i \); where \( (\cdot)^T \) denotes the transpose operator and subscripts \( x, y \) are the horizontal and vertical coordinates of the target. Denoting \( D(\cdot) \) as the PHD at discrete time associated with the multi-target posterior density, the prediction and updating step for the particle PHD filter can be described as follows [17]:

1. Prediction: Drawing survived particles \( \tilde{x}_k^i \) from the predicted particle set and feeding into the prediction model of the particle PHD filter, which is described as [19]

\[
D(x_k|Z_{k-1}) = \int \phi(\tilde{x}_k^i|x_k)D(x_{k-1}|Z_{k-1})d\tilde{x}_k^i + \Upsilon_k(x_k) \tag{1}
\]

where \( \Upsilon_k(\cdot) \) is the intensity function of the new target birth RFS, \( \phi(\cdot) \) is the analogue of the state transition probability in the single target case which is calculated as

\[
\phi(\tilde{x}_k^i|x_k) = \pi(\tilde{x}_k^i|x_k) + \beta(\tilde{x}_k^i|x_k) \tag{2}
\]

for which \( \pi(\cdot) \) is the probability that the targets still exist at time \( k \) and \( \beta(\cdot) \) is the intensity of the RFS for spawned targets. When exploiting the PHD filter with the particle filter, the PHD of the states is represented by the weights of the particles, which include the survived particles and new-born particles. In the traditional particle PHD filter, the particles employed to describe the new-born targets are selected randomly in the video scene, however, to make more accurate prediction, the new-born targets can be obtained by employing a background subtraction step, which is described in [20] in detail. In this case, assuming at time \( k \), \( J_k \) new-born particles are obtained from the background subtraction, the initial weights employed to represent the new-born targets are given as

\[
\tilde{w}_k^i|\{x_k^i\} = \frac{1}{J_k} \tag{3}
\]

then the weights are fed into (1) and to obtain the particle set for the particle PHD prediction.

\[
\{ \tilde{x}_k^i, \tilde{w}_k^i | \}_{i=1}^{N+J_k} \tag{4}
\]

where \( i \) is the index of all particles. The predicted weights from the particle PHD filter prediction step are given as

\[
\tilde{w}_k^i|\{x_k^i\} = \begin{cases} 
\phi(\tilde{x}_k^i|x_k^i)w_k^i_{k-1} \quad i = 1, ..., N \\
\frac{\gamma}{J_k} \quad i = N + 1, ..., N + J_k 
\end{cases} \tag{5}
\]

2. Update: In the application of the particle PHD filter, the PHD \( D(\cdot) \) is represented by the weights of the particles, once the new set of observations is available, we can substitute the approximation of \( D(x_k|Z_{k-1}) \) and the weights of each particle are updated based upon the receipt of the measurements \( Z_k \) as [19]

\[
\tilde{w}_k^i = \left[ p_{M}(\tilde{x}_k^i) + \sum_{\forall z_k \in Z_k} \psi_k(z_k, (\tilde{x}_k^i)) \right] \tilde{w}_k^i|\{x_k^i\} \tag{6}
\]

where

\[
\psi_k(z_k, (\tilde{x}_k^i)) = \frac{N+J_k}{\sum_{i=1}^{N+J_k} \psi_k(z_k, \tilde{x}_k^i)} \tag{7}
\]

and \( \psi_k(z_k, (\tilde{x}_k^i)) = (1-p_{M}(\tilde{x}_k^i))g(z_k|\tilde{x}_k^i) \) is the single target likelihood. In this work, the likelihood of each particle is calculated by histograms of colour and oriented gradient features of human targets [21], by assuming that the noise on the colour and oriented gradient likelihood function is Gaussian

\[
g(z_k|\tilde{x}_k^i) \sim N(z_k; 0, \sigma_g^2) = \frac{1}{\sqrt{2\pi\sigma_g^2}} \exp \left( -\frac{(G(x_k^i))^2}{2\sigma_g^2} \right) \tag{8}
\]

where \( \sigma_g^2 \) is the variance of the noise for the colour and gradient likelihood and \( G(x_k^i) \) is the colour similarities calculated as the Bhattacharyya distance between the reference measurement and the histogram of colour and oriented gradient features \( s(\cdot) \) extracted from the rectangle area centered around the particle location, which can be calculated as

\[
G(x_k^i) = \sqrt{1-s(\tilde{x}_k^i)^T z_k} \tag{9}
\]

After the updating step of the particle PHD filter, the number of targets is calculated by the sum of all the weights for particles as [19]

\[
\hat{M}_k = int \left( \sum_{i=1}^{N+J_k} \tilde{w}_k^i \right) \tag{10}
\]

where \( int(\cdot) \) takes the nearest integer. After calculating the number of targets, a resampling step is employed as described in [2] in order to limit the number of particles, thereby avoiding the number of particles growing exponentially. Then the tracking results \( \{ \tilde{x}_k^i \}_{i=1}^{M_k} \) are obtained from the particle PHD filter, where \( (\cdot)^\top \) denotes the states from the PHD filtering algorithm.

B. Particle Retro-PHD Filtering

The Retro-PHD filter is employed to use more measurements beyond the current time by processing information from later stages in an approximate manner, and can achieve more accurate tracking results. Similar to forward particle PHD filtering, the retrodiction step is also generalized by the RFS [9] [8]. The algorithm is concerned with the density at time \( t = k - L \), where \( L \) is the time lag. When employing the particle Retro-PHD filter, the retrodicted particle weights at time \( t \) are evaluated using the backward iterations using filter outputs \( \{ \tilde{x}_k^i \}_{i=1}^{N} \) for \( t = k-L, ..., k \). The particle weights
from the backward filtering stage are computed as derived in \cite{8}:

$$w_{l|k}^{f} = \hat{w}_{l}^{f} \left[ e^{(\mathcal{X}_{l}^{f})} \sum_{q=1}^{N} \frac{\tilde{\mu}_{t+1|l}^{q}\tilde{\nu}_{t+1|l}(\mathcal{X}_{l}^{f})}{\tilde{\mu}_{t+1|l}} + (1 - e(\mathcal{X}_{l}^{f})) \right] (11)$$

where

$$\mu_{t+1|l}^{q} = \Upsilon_{t+1}(\mathcal{X}_{t+1}^{f}) + \sum_{r=1}^{N} \hat{w}_{t}^{r} \times e(\mathcal{X}_{t+1}^{r})(\mathcal{X}_{t+1}^{f}) \right]$$

and the conversion function is given as:

$$f_{l|t-1}(\mathcal{X}_{l}^{f}|\mathcal{X}_{t-1}^{f}) = \frac{\exp \left( -\left( \mathcal{X}_{l}^{f} - \mathcal{F}(\mathcal{X}_{t-1}^{f}) \right)^{T} \frac{1}{2} \sigma_{f}^{2} \right)}{\sqrt{\det(2\pi\sigma_{f}^{2})}} (13)$$

where $\sigma_{f}^{2}$ is the variance of the conversion function and $\mathcal{F}(\cdot)$ is the state transformation matrix. After obtaining the particle set $\{ \mathcal{X}_{l}^{f}, \hat{w}_{l}^{f} \}_{l=1}^{N}$ from the particle Retro-PHD filter, the number and states of the human targets are obtained in the same way as described in Section II-A and in order to mitigate the effects of particle depletion, a resampling step is employed as described in \cite{9}. The tracking results from the particle Retro-PHD filter are represented as $\{ \mathcal{X}_{k}^{m} \}_{m=1}^{M_{k}}$.

III. ADAPTIVE SOLUTION FOR PARTICLE RETRO-PHD FILTER

From the above steps, results from both the forward and backward filtering process are obtained, in which the forward measurements are utilized in the filtering algorithm and backward measurements are utilized in the retrodiction algorithm to estimate the target states, which are represented with the black lines and the blue lines in the graphical representation in Fig. 1, respectively. As mentioned in Section II-B, an adaptive particle Retro-PHD filter can be described as Algorithm 1.

IV. SIMULATION

In order to evaluate the performance of the proposed adaptive particle Retro-PHD filter, sequences from the CAVIAR and PETS2009 datasets are employed, where in the CAVIAR dataset, 3-5 human targets are walking in a shopping mall environment and in the PETS2009 dataset, 3-6 human targets are walking in a campus environment, and these include human target occlusion, appearing and disappearing randomly in the scene. In this work, 1000 particles are employed to represent targets in the CAVIAR dataset and 1500 particles are employed in the PETS2009 dataset; 200 particles are employed for new-born targets in each frame. Following previous experience, as in \cite{20}, the zero-mean noise vector $w_{k}$ for prediction in the state model has covariance structure.
Algorithm 1  Adaptive Retro-PHD filter

Input: \( \{x_{k-1}^{i}, u_{k-1}^{i}\}_{i=1}^{N} \)

Output: \( \{\hat{x}_{k-1}^{i}\}_{i=1}^{M_{k-1}} \)

1: Forward Filtering
2: Select new-born particles from background subtraction as described in [20].
3: Particle prediction by (1).
4: Obtain prediction weights by (5).
5: for \( i = 1 : N + J_k \) do
6: Calculate \( g(z_{k} | \hat{x}_{k}^{i}) \) by (6).
7: Update particle weights with (6).
8: end for
9: Calculate target number by (10).
10: Resample updated particles and discard \( J_k \) particles with lowest weights with resampling step described in [9].
11: Data association for survived and new-born particles.
12: Clustering with K-means and obtain \( \{\hat{x}_{k}^{m}\}_{m=1}^{M_k} \).
13: Backward Retrodiction
14: for \( i = 1 : N \) do
15: if \( x_{k}^{i} \in \text{survived particles} \) then
16: Calculate \( f(\cdot) \) following (13).
17: end if
18: Calculate retrodiction weight with (11).
19: end for
20: Clustering with K-means and obtain \( \{\hat{x}_{k-1}^{m}\}_{m=1}^{M_{k-1}} \).
21: Adaptive Recursion
22: Obtain the measurement set \( Z_{k} \).
23: for \( m = 1 : M_{k-1} \) do
24: Calculate filtering and retrodiction weight \( \lambda \) by (16).
25: Make correction for tracking position with \( \lambda \) by (17).
26: end for
27: Clustering with K-means and obtain \( \{\hat{x}_{k-1}^{m}\}_{m=1}^{M_{k-1}} \).

\( \text{cov}\{w_{k}\} = \text{diag}\{25, 25, 16, 16, 4, 4\} \) and for \( v_{k}, \text{cov}\{v_{k}\} = \text{diag}\{25, 25\} \). The missed detection probability \( P_M = 0.01 \), the survival probability \( e = 0.99 \), the new born intensity is given as \( \bar{Y} = 0.1 \) and clutter intensity \( \kappa = 0.01 \). The variance for conversion function \( \sigma_{v}^2 \), likelihood function \( \sigma_{g}^2 \) and \( \lambda \) function \( \sigma_{\lambda}^2 \) are set empirically to be 25, 36 and 25 respectively. In order to reduce the computational complexity, the time lag \( \Lambda \) is set to be 1.

| TABLE I | MEE COMPARISONS OF DIFFERENT TRACKING RESULTS |
|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|
| CAVIAR | PHD | R-PHD | A-PHD | PHD | R-PHD | A-PHD |
| ME (pixel) | 34.85 | 28.43 | 25.71 | 43.08 | 36.49 | 34.95 |
| Improvement (%) | - | 18.42% | 26.23% | - | 15.30% | 18.87% |

In order to evaluate the proposed tracking approach, the mean of the Euclidean error (ME) between tracking results and the ground truth is compared and shown in Table I, where PHD denotes the results from the PHD filter (i.e. the forward filtering step in Algorithm 1), R-PHD denotes the Retro-PHD (i.e. forward filtering + the backward retrodiction step in Algorithm 1) and A-PHD denotes our proposed adaptive Retro-PHD filtering algorithm (i.e. the whole Algorithm 1).

V. Conclusion

In this work, we use the term retrodiction PHD filtering in recognition of the approximation error in the PHD smoother, and propose an adaptive retrodiction step for the particle PHD filter with the aid of forward and backward measurements motivated by interacting adaptive filters. The results show the improvement by the proposed method over the conventional particle Retro-PHD filter both in terms of the localization and cardinality through the mean of the Euclidean error on each frame and OSPA measure, where the OSPA value is reduced by 29% for the CAVIAR dataset and 18% for the PETS2009 dataset. In future work, more extensive evaluation and comparisons will be performed.
